SDDM_2014. 0. 4. 4. 2. 1. 199. Cite SIPIN 4.. The remainder of this paper is organized in three sections. The first section reviews some of the major findings of the benefits of extensibility across modeling frameworks. The second section provides a discussion of the key concepts and features of Slide and some of its extensions. The third section. 38 . 5.. 5. 37. . Toon Boom USAnimation Opus 6.. SOCKET. 19. The fourth section is a discussion of some of the early engineering case studies that utilized Slide and some of its applications in the design of rock slopes and ice dams for the Upper Michigan River Ice Dam Complex.. 6. PcaRisk 5.. 7. e.. 6.3.3. 6.06. . The remaining paper of the chapter is divided into five sections. The first is an organizational chapter that lays out the context of the study and notes some of the benefits of extensibility across model analysis and design tools. An introductory section to Slide, highlights the key features that are relevant to the study.. 37. Analysis of aquifer recharge potential: Incorporation of regional scale hydrology into an aquifer (Incorporation of regional scale hydrology into an aquifer (Incorporation of regional scale hydrology into an aquifer 37 Figure 1: Slope stability model for traditional engineering analysis of deep quaternary alluvial and composite rock slopes using the Slide software. The remainder of the chapter is organized into the different steps and proceedings of Slide. The chapter begins with a general review of rock slide modeling and Slide. In this review section, we note some of the key features of the software and its potential utility. A discussion of early engineering design cases is then provided. Next, the first engineering design case is presented and analyzed in detail. This case includes the design of a composite underground storage cavern in granite and the removal of granite rock and soil. A discussion of the sources of error in slide analysis is then provided. An analysis of the potential errors in rock slide analysis is then provided and includes a discussion of the major sources of errors. The last two sections of the chapter are divided into discussions of key steps and results of the analysis. The first section is the step analysis. This section identifies and discusses the important steps in the slide

Timescale/age identification of rock layers from few short timepoint datapoints: A comparative study of two methods What is already known on this topic? Existing methods of identifying the age of rock are relatively unreliable. Bedrock (solid) is only one component of geological time. The other components are fluid (water and mud) and gas. Rock (fluid and gas) is deformed in geological time and the manner in which it does so results in a range of age indicators. What is the difference between this article and other methods? This article addresses the problem of identifying the age of sedimentary rocks using a small number of dated thin sections. This problem is commonplace in the pre-exploration and prospecting period and in a range of other situations. Methods Benchmark There is a range of commonly used methods of identifying the age of sedimentary rocks. We will consider two examples: (i) bright line texture analysis and (ii) calculation of the age of a parent dyke. Bright Line Texture Analysis We use the terms 'gut' and 'gutline' loosely as opposed to the technical sense in which these terms are used in geology. We will use the term 'gut' to refer to the visible, macroscopic, structural/tectonic characteristics of a rock and, more specifically, to be the result of a dynamic tectonic process. Gut features include but are not limited to: 1. crinkle fractures; 2. swelling; 3. troughs; 4. cleavage; 5. folding; 6. foliation; 7. grain size; 8. gouges; 9. jointing; 10. porphyritic cleavage; 11. pseudomorphs; and 12. strike-slip faults A 'gutline' or 'gutline structure' is a visible, macroscopic, structural feature associated with a micro-level tectonic process, such as faulting or folding. In geology, the terms 'gut' and 'gutline' are used interchangeably. They can be misleading because they suggest that all the visible features of a sedimentary rock are caused by the same tectonic process. This is a fallacy; there are many distinct tectonic processes that produce particular visual features
